Sandwich DSL Case Study (Scala)

Introduction

Few computer science graduates will design and implement a general-purpose programming language during their careers. However, many graduates will

design and implement—and all likely will use—special-purpose languages in their work.

These special-purpose languages are often called *domain-specific languages* (or DSLs). For more discussion of DSL concepts and terminology, see the accompanying notes on Domain-Specific Languages.

In this case study, we design and implement a simple *internal DSL*. This DSL describes simple "programs" using a set of Scala algebraic data types. We express a program as an *abstract syntax tree* using the DSLs data types.

The case study first builds a package of functions for creating and manipulating the abstract syntax trees. It then extends the package to translate the abstract syntax trees to a sequence of instructions for a simple "machine".

Building the DSL

Suppose Emerald de Gassy, the owner of the Oxford-based catering business Deli-Gate, hires us to design a domain-specific language (DSL) for describing sandwich platters. The DSL scripts will direct Deli-Gate's robotic kitchen appliance SueChef (Sandwich and Utility Electronic Chef) to assemble platters of sandwiches.

In discussing the problem with Emerald and the Deli-Gate staff, we discover the following:

- A sandwich platter consists of zero or more sandwiches. (Zero? Why not! Although a platter with no sandwiches may not be a useful, or profitable, case, there does not seem to be any harm in allowing this degenerate case. It may simplify some of the coding and representation.)

- Each sandwich consists of layers of ingredients.

- The categories of ingredients are breads, meats, cheeses, vegetables, and condiments.

- Available breads are white, wheat, and rye.

- Available meats are turkey, chicken, ham, roast beef, and tofu. (Okay, tofu is not a meat, but it is a good protein source for those who do not wish to eat meat. This is a college town after all. Oh, there is also a special meat served for football games Thanksgiving week called "bulldog", but it is really just chicken, so we can ignore that choice for our purposes here.)

- Available cheeses are American, Swiss, jack, and cheddar.

- Available vegetables are tomato, lettuce, onion, and bell pepper.

- Available condiments are mayo, mustard, relish, and Tabasco. (Of course, this being the South, the mayo is Blue Plate Mayonnaise and the mustard is a Creole mustard.)

Let's define this as an internal DSL—in particular, by using a relatively *deep embedding.*

What is a sandwich? ... Basically, it is a stack of ingredients.

Should we require the sandwich to have a bread on the bottom? ... Probably. ... On the top? Maybe not, to allow "open-faced" sandwiches. ... What can the SueChef build? ... We don't know at this point, but let's assume it can stack up any ingredients without restriction.

For simplicity and flexibility, let's define a Scala data type `Sandwich` to model sandwiches. It wraps a possibly empty list of ingredient layers. *We assume the head of the list to be the layer at the top of the sandwich.*

```scala
case class Sandwich(sandwich: List[Layer])
```

Note: In this case study, we implement Scala algebraic data type constructors (i.e., product types) as `case class` or `case object` entities. We implement union types using a `trait` with subtypes for the variants.

Data type `Sandwich` gives the specification for a sandwich. When "executed" by the SueChef, it results in the assembly of a sandwich that satisfies the specification.

As defined, the `Sandwich` data type does not require there to be a bread in the stack of ingredients. However, we add function `newSandwich` that starts a sandwich with a bread at the bottom and a function `addLayer` that adds a new ingredient to the top of the sandwich. We leave the implementation of these functions as exercises.

```scala
def newSandwich(b: Bread): Sandwich
def addLayer(s: Sandwich)(x: Layer): Sandwich
```

Ingredients are in one of five categories: breads, meats, cheeses, vegetables, and condiments.

Because both the categories and the specific type of ingredient are important, we choose to represent both in the type structures and define the following types. A value of type `Layer` represents a single ingredient. Type `Layer` has five variants (subtypes) `Bread`, `Meat`, `Cheese`, `Vegetable`, and `Condiment`. Each of these variants itself has several variants. For example, `Bread` has variants (subtypes) `White`, `Wheat`, and `Rye`.

```scala
sealed trait Layer

sealed trait Bread      extends Layer
case object White       extends Bread
case object Wheat       extends Bread
case object Rye         extends Bread

sealed trait Meat       extends Layer
```

```scala
case object Turkey     extends Meat
case object Chicken    extends Meat
case object Ham        extends Meat
case object RoastBeef  extends Meat
case object Tofu       extends Meat

sealed trait Cheese    extends Layer
case object American   extends Cheese
case object Swiss      extends Cheese
case object Jack       extends Cheese
case object Cheddar    extends Cheese

sealed trait Vegetable extends Layer
case object Tomato     extends Vegetable
case object Onion      extends Vegetable
case object Lettuce    extends Vegetable
case object BellPepper extends Vegetable

sealed trait Condiment extends Layer
case object Mayo       extends Condiment
case object Mustard    extends Condiment
case object Ketchup    extends Condiment
case object Relish     extends Condiment
case object Tabasco    extends Condiment
```

We need to be able to compare ingredients for equality and convert them to strings. Because the automatically generated definitions are appropriate, we do not need to do anything further.

We will need to provide an appropriate definition of equality for `Sandwich` because the default element-by-element equality of lists does not seem to be the appropriate equality comparison for sandwiches.

To complete the model, we define type `Platter` to wrap a list of sandwiches.

```scala
case class Platter(platter: List[Sandwich])
```

We also define functions `newPlatter` to create a new `Platter` and `addSandwich` to add a sandwich to the `Platter`. We leave the implementation of these functions as exercises.

```scala
def newPlatter: Platter
def addSandwich(p: Platter)(s: Sandwich): Platter
```

Exercise Set A

Please put these functions in a Scala module `SandwichDSL`. You may use functions defined earlier in the exercises to implement those later in the exercises.

1. Define and implement the Scala functions `newSandwich`, `addLayer`, `newPlatter`, and `addSandwich` described above.

2. Define and implement the Scala query functions below that take an ingredient (i.e., `Layer`) and return `true` if and only if the ingredient is in the specified category.

   ```scala
   def isBread(x: Layer): Boolean
   def isMeat(x: Layer): Boolean
   def isCheese(x: Layer): Boolean
   def isVegetable(x: Layer): Boolean
   def isCondiment(x: Layer): Boolean
   ```

3. Define and implement a Scala function `noMeat` that takes a sandwich and returns `true` if and only if the sandwich contains no meats.

   ```scala
   def noMeat(x: Sandwich): Boolean
   ```

4. According to a proposed City of Oxford ordinance, in the future it may be necessary to assemble all sandwiches in *Oxford Standard Order (OSO)*: a slice of bread on the bottom, then zero or more meats layered above that, then zero or more cheeses, then zero or more vegetables, then zero or more condiments, and then a slice of bread on top. The top and bottom slices of bread must be of the same type.

   Define and implement a Scala function `inOSO` that takes a sandwich and determines whether it is in OSO and another function `intoOSO` that takes a sandwich and a default bread and returns the sandwich with the same ingredients ordered in OSO.

   ```scala
   def inOSO(s: Sandwich): Boolean
   def intoOSO(s: Sandwich)(defaultbread: Bread): Sandwich
   ```

   Hint: Remember library functions like `dropWhile`.

   Note: It is impossible to rearrange the layers into OSO if the sandwich does not include exactly two breads of the same type. If the sandwich does not include any breads, then the default bread type (second argument) should be specified for both. If there is at least one bread, then the bread type nearest the *bottom* can be chosen for both top and bottom.

5. Assuming that the price for a sandwich is the base price plus the sum of the prices of the individual ingredients, define and implement a Haskell function `priceSandwich` that takes a price list, a base price, and a sandwich and returns the price of the sandwich.

   ```scala
   def priceSandwich(pl: List[(Layer,Int)], base: Int)(s: Sandwich): Int
   ```

   Use the following price list as a part of your testing:

   ```scala
   val prices = List(
       (White,20),(Wheat,30),(Rye,30),
   ```

```
                    (Turkey,100),(Chicken,80),(Ham,120),(RoastBeef,140),(Tofu,50),
                    (American,50),(Swiss,60),(Jack,60),(Cheddar,60),
                    (Tomato,25),(Onion,20),(Lettuce,20),(BellPepper,25),
                    (Mayo,5),(Mustard,4),(Ketchup,4),(Relish,10),(Tabasco,5)
                )
```

6. Define and implement a Scala function `eqSandwich` that compares two sandwiches for equality.

   What does equality mean for sandwiches? Although the definition of equality could differ, you can use "bag equality". That is, two sandwiches are equal if they have the same number of layers (zero or more) of each ingredient, regardless of the order of the layers.

   ```
   def eqSandwich(sl: Sandwich)(sr: Sandwich): Boolean
   ```

Compiling the Program for the SueChef Controller

In this section, we look at compiling the `Platter` and `Sandwich` descriptions to issue a sequence of commands for the SueChef's controller.

The SueChef supports the special instructions that can be issued in sequence to its controller. The algebraic data type `SandwichOp` below represents the instructions.

```scala
sealed trait SandwichOp
case object StartSandwich extends SandwichOp
case object FinishSandwich extends SandwichOp
case class  AddBread(bread: Bread) extends SandwichOp
case class  AddMeat(meat: Meat) extends SandwichOp
case class  AddCheese(cheese: Cheese) extends SandwichOp
case class  AddVegetable(vegetable: Vegetable) extends SandwichOp
case class  AddCondiment(condiment: Condiment) extends SandwichOp
case object StartPlatter extends SandwichOp
case object MoveToPlatter extends SandwichOp
case object FinishPlatter extends SandwichOp
```

We also define the type `Program` to represent the sequence of commands resulting from compilation of a `Sandwich` or `Platter` specification.

```scala
case class Program(program: List[SandwichOp])
```

The flow of a program is given by the following pseudocode:

```
StartPlatter
for each sandwich needed
    StartSandwich
    for each ingredient needed
        Add ingredient on top
```

```
            FinishSandwich
            MoveToPlatter
    FinishPlatter
```

Consider a sandwich defined as follows:

```
Sandwich(List(Bread Rye,Condiment Mayo,Cheese Swiss,
                Meat Ham,Bread Rye))
```

The corresponding sequence of SueChef commands would be the following.

```
List(StartSandwich,AddBread Rye,AddMeat Ham,AddCheeseSwiss,
    AddCondiment Mayo,AddBread Rye,FinishSandwich,MoveToPlatter)
```

Exercise Set B

1. Define and implement a Scala function `compileSandwich` to convert a sandwich specification into the sequence of SueChef commands to assemble the sandwich.

   ```
   def compileSandwich(s: Sandwich): List[SandwichOp]
   ```

2. Define and implement a Scala function `compile` to convert a platter specification into the sequence of SueChef commands to assemble the sandwiches on the platter.

   ```
   def compile(p: Platter): Program
   ```

Source Code

The Scala source code for this case study is in file `SandwichDSL_base.scala`.

Acknowledgements

In Spring 2018, I recreated this separate Scala-based version of the case study by combining aspects of Spring 2018 Haskell-based version with the Scala-based version from Spring 2016.

I maintain these notes as text in Pandoc's dialect of Markdown using embedded LaTeX markup for the mathematical formulas and then translate the notes to HTML, PDF, and other forms as needed. The HTML version of this document may require use of a browser that supports the display of MathML.
